Outline

- Introduction
 - Environmental standard setting
 - Hierarchical structure of a toxicity data set
- Solutions:
 - Weighted hierarchical (bootstrap) model
 - Weighted non-hierarchical (bootstrap) model
- Discussion
- Conclusions

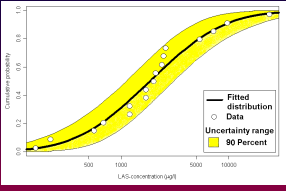

Variability <=> uncertainty

Variability:

- true heterogeneity
- not reducible through further measurements

Uncertainty:

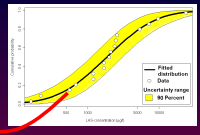

- ignorance, partial knowledge
- partly reducible through further measurements

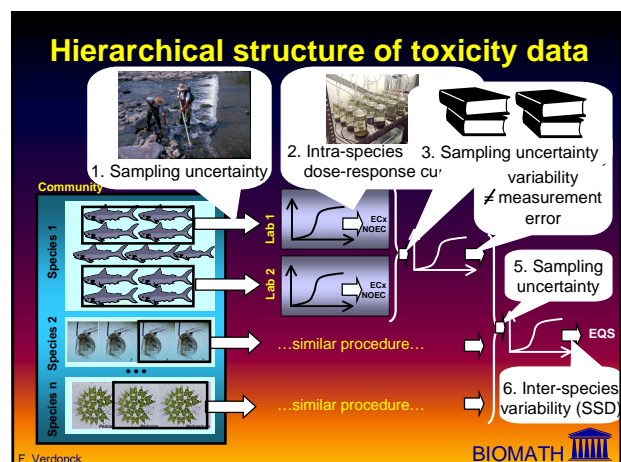

Introduction

- Toxicity data are hierarchical in structure:
 - NOEC: No Effect Concentration
 - ECx: x % Effect Concentration
 - Other summary statistics ...
- A lot of information is discarded/lost
- Goal:
 - How to account for this extra info in a SSD?
 - Should a hierarchical or nonhierarchical model be used?

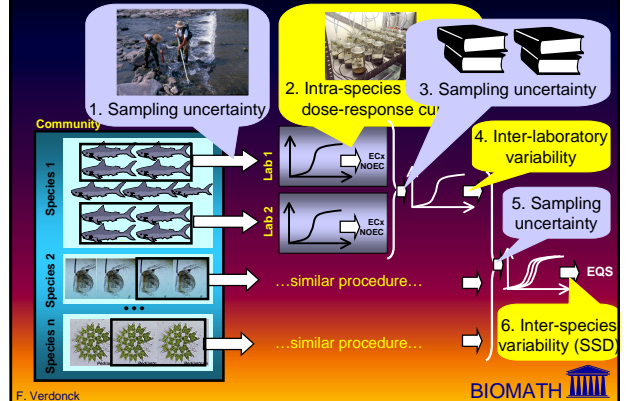

'Usual' approach based on summary data

Goal: base on all raw data

Weighting toxicity data

> To avoid over/under-representation of a species, laboratory, individual!

Weighting toxicity data (cont'd)

- Shape of the curve changes (shift)
- Uncertainty band changes in width

First solution: hierarchical models

Several types:

- nonparametric <> parametric
- Bayesian <> frequentist
- analytical <> numerical

All these have their advantages and disadvantages.

Main focus here is hierarchical or NOT?

Weighted hierarchical bootstrap

1. Sample the species
2. Sample the laboratories
3. Sample the individuals

Second solution: non-hierarchical model

Community

- Ignore hierarchical structure of variabilities and treat all **raw** data (no summary statistics!) on same level
- No hierarchical method but easier to understand and apply

F. Verdonck

BIOMATH

Example: Cu

'Usual approach'

- Inter-species variability
- Sampling uncertainty (only 5.)

Hierarchical Model

- Inter-species + inter-laboratory (+ intra-species variability)
- 'Aggregated' sampling uncertainty

Non-hierarchical model

- Inter-species + inter-laboratory (+ intra-species variability)
- Uncertainty difficult to interpret

F. Verdonck

BIOMATH

Validation

- Test
 - bias = estimated 5th percentile - true 5th percentile
 - coverage of confidence/uncertainty interval
- Simulation study with realistic, hypothetical data set:
 - 30 species from which 10 were sampled
 - Each species has specified inter-lab distribution
 - No assumption on inter-species distribution (top level)

F. Verdonck

BIOMATH

Validation

- Simulation study with realistic, hypothetical data set:
 - 30 species from which 10 were sampled
 - Each species has specified inter-lab distribution
 - No assumption on inter-species distribution (top level)

F. Verdonck

BIOMATH

Preliminary results

	Raw/all data	
	Hierarchical Model	Non-hierarchical Model
Mean bias	-0.3	-0.9
Variation bias	1.4	1.4
Coverage of 90% CI	~ 93%	~ 80%

F. Verdonck

BIOMATH

Preliminary results

	Summary data	Raw/all data	
	'Usual' approach	Hierarchical Model	Non-hierarchical Model
Mean bias	19.3	-0.3	-0.9
Variation bias	6.1	1.4	1.4
Coverage of 90% CI	~ 0%	~ 93%	~ 80%

Validation problem

F. Verdonck

BIOMATH

Issue validation

- Can bias be separated in $\text{bias}_{\text{model}}$ and $\text{bias}_{\text{summary} \leftrightarrow \text{all data}}$?
- Model assumption on top level?

F. Verdonck BIOMATH

Issue validation (true 5th percentile?)

> implications for the hypothetical assumptions

- bottom-up: is inter-lab truth and resulting inter-species following from that?
- top-down: is inter-species truth and inter-lab additional?

F. Verdonck BIOMATH

Discussion

	Summary data	Raw/all data	
	'Usual' approach	Hierarchical Model	Non-hierarchical Model
5 th -percentile	+	+++	++
Practical Use	+++	+	+++
Interpretation of Confidence band	+	+++	-

F. Verdonck BIOMATH

Conclusions

- To incorporate intra-species and inter-laboratory variability into a Species Sensitivity Distribution, a weighted non-hierarchical model is sufficiently accurate and easy-to-use.
- To incorporate several levels of sampling uncertainties, a weighted hierarchical model is more appropriate.
- Difficult to validate.
